

**CM-triviality  
and  
Geometric Elimination of Imaginaries**

## 1 Introduction

Hrushovski gave a counterexample to the Zilber's conjecture on strongly minimal sets by **Generic Relational Structures**, i.e. relational countable structures constructed by amalgamating relational finite structures.

**Generic relational structures are usually ...**

**CM-TRIVIAL.**

To show the CM-triviality of generic structures, we needed two steps.

- 1st step:  
Show weak elimination of imaginaries.
- 2nd step:  
Working in the real sort, show CM-triviality.

Following these two steps,

I proved CM-triviality of  
Herwig's weight  $\omega$  small theory, and  
Baldwin-Shi's stable generic structures.

A question comes up :

Is there a way to show CM-triviality **without showing Weak Elimination of Imaginaries?**

**I find the following answer.**

## THE MAIN RESULT

In simple theories with elimination of hyper-imaginaries,

CM-triviality **in the real sort** (I will define)

↓

Geometric elimination of imaginaries

+

CM-triviality in the original sense, firstly introduced by Hrushovski.

## 2 Set-up

From now on, let  $T$  be a simple theory with elimination of hyperimaginaries and  $\overline{M}$  be a sufficiently saturated model of  $T$ .

(Hyper-)imaginary elements are equivalence classes of (type-)definable equivalence relations.

We work in  $\overline{M}^{\text{eq}}$ , the eq-structure, consisting of imaginary elements.

### 3 CM-triviality

#### Hrushovski's Definition for CM-triviality

$T$  is CM-trivial, if for any  $a, A, B \subset \overline{M}^{\text{eq}}$  with  $\text{acl}^{\text{eq}}(aA) \cap \text{acl}^{\text{eq}}(B) = \text{acl}^{\text{eq}}(A)$ ,

$$\text{Cb}(\text{stp}(a/A)) \subseteq \text{acl}^{\text{eq}}(\text{Cb}(\text{stp}(a/B))).$$

- $\text{acl}^{\text{eq}}(*)$  denotes algebraic closure in  $\overline{M}^{\text{eq}}$

Equivalently,

for any  $a$ ,  $A = \text{acl}^{\text{eq}}(A)$ ,  $B = \text{acl}^{\text{eq}}(B) \subset \overline{M}^{\text{eq}}$ ,

$$a \downarrow_A B \Rightarrow a \downarrow_{A \cap \text{acl}^{\text{eq}}(a, B)} B.$$

- We are working in the eq-structure,  
not in the real sort.

## My Definition for CM-triviality

T is CM-trivial **in the real sort**, if,  
for any  $\bar{a}$ ,  $A = \text{acl}(A)$ ,  $B = \text{acl}(B) \subset \bar{M}$ ,

$$\bar{a} \downarrow_A B \Rightarrow \bar{a} \downarrow_{A \cap \text{acl}(\bar{a}, B)} B.$$

- Notice that everything is **in the real sort**.

## IND/I

T has the independence over intersections (IND/I),  
if, for any  $\bar{a}$ ,  $A = \text{acl}(A)$ ,  $B = \text{acl}(B) \subset \bar{M}$

$$\bar{a} \downarrow_A B, \quad \bar{a} \downarrow_B A \Rightarrow \bar{a} \downarrow_{A \cap B} AB.$$

- Notice that everything is **in the real sort**.

Proposition A

CM-triviality **in the real sort**  $\Rightarrow$  IND/I.

The key point of the proof: Assume  $\bar{a} \downarrow_A B$ ,  $\bar{a} \downarrow_B A$ ,  $A = \text{acl}(A)$ ,  $B = \text{acl}(B)$ .

By  $\bar{a} \downarrow_B AB$ ,  $\text{acl}(\bar{a}, B) \cap AB = B$  follows.  
So we have

$$B \cap A \subseteq \text{acl}(\bar{a}, B) \cap A \subseteq (\text{acl}(\bar{a}, B) \cap AB) \cap A \subseteq B \cap A.$$

By CM-triviality in the real sort, we have

$$\bar{a} \downarrow_{\text{acl}(\bar{a}, B) \cap A} B.$$

Proposition B      IND/I  $\Leftrightarrow$  GEI.

Geometric Elimination of Imaginaries

means that

for any  $\mathbf{i} \in \overline{M}^{\text{eq}}$ , there exists  $\bar{\mathbf{a}} \subset \overline{M}$  such that

$$\mathbf{i} \in \text{acl}^{\text{eq}}(\bar{\mathbf{a}}),$$

$$\bar{\mathbf{a}} \in \text{acl}^{\text{eq}}(\mathbf{i}).$$

The proof of “**IND/I**  $\Rightarrow$  **GEI**.”

Fix  $\mathbf{i} = \bar{a}_E$ . Take  $\bar{b}, \bar{c}$  such that  $\bar{b}, \bar{c} \models \text{tp}(\bar{a}/\mathbf{i})$  and  $\bar{a}, \bar{b}, \bar{c}$  are independent over  $\mathbf{i}$ .

By  $\bar{a} \downarrow_{\bar{b}} \bar{c}, \bar{a} \downarrow_{\bar{c}} \bar{b}$  and **IND/I**, we have

$$\bar{a} \quad \downarrow \quad \bar{b}, \bar{c}. \\ \text{acl}(\bar{b}) \cap \text{acl}(\bar{c})$$

Let  $\mathbf{A} = \text{acl}(\bar{b}) \cap \text{acl}(\bar{c})$ .

As  $\mathbf{i} \in \text{dcl}^{\text{eq}}(\bar{a})$ , we have “ $\mathbf{i} \in \text{acl}^{\text{eq}}(\mathbf{A})$ ”.

By  $\bar{b} \downarrow_{\mathbf{i}} \bar{c}$ , we see “ $\mathbf{A} \subseteq \text{acl}^{\text{eq}}(\mathbf{i})$ ”.

Under GEI,  
CM-triviality **in the real sort**=CM-triviality.

Main Theorem

CM-triviality **in the real sort**  
↓  
GEI+CM-triviality.

## Two Remarks

(1) Simple generic structures have the following NICE characterization of non-forking;

$$\mathbf{A} \downarrow_{\mathbf{A} \cap \mathbf{B}} \mathbf{B} \Leftrightarrow \mathbf{A} \otimes_{\mathbf{A} \cap \mathbf{B}} \mathbf{B} = \mathbf{A} \cup \mathbf{B} = \text{cl}_{\overline{\mathbf{M}}}(\mathbf{A} \cup \mathbf{B})$$

for any  $\mathbf{A} = \text{acl}(\mathbf{A}), \mathbf{B} = \text{acl}(\mathbf{B}) \subset \overline{\mathbf{M}}$ .

From this, we can check that simple generic structures are CM-trivial **in the real sort**.

**Main Theorem directly** shows the CM-triviality of simple generic structures.

(2)

CM-triviality **in the real sort**

$\nleftrightarrow$

CM-triviality in the original sense.

In [E], D.Evans gave an  $\omega$ -categorical  $SU = 1$  CM-trivial structure  $\mathcal{C}$  without WEI interpreted in an  $\omega$ -categorical  $SU = 2$  generic binary graph. I checked  $\mathcal{C}$  does not have GEI.

Remark on IND/I

In pregeometric surgical theories,  $\text{IND/I} \Rightarrow \text{GEI}$ .

In O-minimal case, “ $\text{IND/I} \Rightarrow \text{EI}$ ” **only** holds.

## ENDING : 4 Problems on CM-triviality

- (1) In stable theories, does CM-triviality imply CM-triviality **in the real sort**?

(2) Is any superstable CM-trivial theory  $\omega$ -stable?

This is a generalization of Baldwin's  
**Problem:** Is any superstable  $\omega$ -saturated generic structure  $\omega$ -stable?

(3) Recall that n-ampleness is defined in the eq-structures.

non-1-ampleness  $\Leftrightarrow$  One-basedness  $\Rightarrow$   
non-2-ampleness  $\Leftrightarrow$  CM-triviality  $\Rightarrow$   
non-3-ampleness  $\Rightarrow$  non-4-ampleness  $\Rightarrow \dots$

- Define non-3-ampleness **in the real sort**.  
And does it imply GEI?

(4) In Zariski geometries, local modularity is equivalent to CM-triviality.

- In O-minimal theories,  
is local modularity equivalent to CM-triviality?
