BY

#### Abstract

Call a function differentiable at some rate if the difference quotient approximates the derivative at this rate. Consider some root of the density of a one-parameter family of probability measures as a function of the parameter. We characterize differentiability of this root in some (not necessarily corresponding) mean at a certain rate by an appropriate differentiability of an arbitrary other root at the same rate. In particular, we characterize Hellinger differentiability at some rate in terms of differentiability of the densities. This allows us to compare Hellinger differentiability at some rate with a differentiability concept of Pfanzagl and Wefelmeyer [11], which is necessary and sufficient for local asymptotic normality in the i.i.d. case at a certain rate.

## 1. INTRODUCTION

Let $P_{t}, t \in R$, be a family of mutually absolutely continuous probability measures on a measurable space $(X, \mathscr{A})$. Fix $P=P_{0}$, and let $f_{t}$ denote a $P$ density of $P_{t}$. We want to compare several approaches to define differentiability of $f_{t}$ at $t=0$. Our aim is to decide which of these concepts is most appropriate for obtaining "higher order" local asymptotic normality in the i.i.d. case. More precisely, we are interested in the following particular form of the local asymptotic normality. For every bounded sequence $u_{n}$, $n \in N$, the log-likelihood ratios can be written as

$$
\begin{equation*}
\sum_{v=1}^{n} \log f_{n^{-1 / 2} u_{n}}\left(x_{v}\right)=u_{n} n^{-1 / 2} \sum_{v=1}^{n} g\left(x_{v}\right)-\frac{1}{2} u_{n}^{2} \sigma^{2}+R_{n}(x) \tag{1.1}
\end{equation*}
$$

with $n^{-1 / 2} \sum_{v=1}^{n} g\left(x_{v}\right)$ asymptotically normal $N\left(0, \sigma^{2}\right)$ under $P^{n}$, and $R_{n} \rightarrow 0$ in $P^{n}$-probability.

To examine higher order properties of statistical procedures, we require rates on $R_{n} \rightarrow 0$ of the form

$$
\begin{equation*}
P^{n}\left\{\left|R_{n}\right|>\varepsilon n^{-a / 2}\right\}=o\left(n^{-b / 2}\right) \quad \text { for every } \varepsilon>0 \tag{1.2}
\end{equation*}
$$

For $a \leqslant 1$ and $b=2 a$, such rates are needed by Bickel et al. [2] to
prove that a test statistic is efficient of order $o\left(n^{-a}\right)$ if it approximates the $\log$-likelihood ratio up to $o\left(n^{-a / 2}\right)$.

For $a=b=0$, condition (1.2) means that $R_{n} \rightarrow 0$ in $P^{n}$-probability. It is known (see [6] and [7]) that local asymptotic normality in the sense of (1.1) holds if and only if $f_{t}^{1 / 2}$ is differentiable in quadratic mean at $t=0$. This means that there exists a derivative $\frac{1}{2} g$ such that

$$
\begin{equation*}
f_{t}^{1 / 2}=1+t \frac{1}{2} g+t r_{t} \quad \text { with } P\left(r_{t}^{2}\right)=o\left(t^{0}\right) \tag{1.3}
\end{equation*}
$$

(Here $P(f)$ stands for $\int f(x) P(d x)$.)
For arbitrary $a, b$, however (and under the assumptions $P(g)=0$ and $\left.P\left(|g|^{2(2+b) /(2-a)}\right)<\infty\right)$, Pfanzagl and Wefelmeyer [11] found a somewhat different differentiability concept to be necessary and (nearly) sufficient for (1.2) (in the sense that it implies (1.2) for every $a^{\prime}<a$ instead of $a$ ). This is the so-called $\mathrm{DCC}_{b}$-differentiability of $f_{t}$ at a rate $o\left(t^{a}\right)$, defined by

$$
\begin{equation*}
f_{t}=1+t g+t^{1+a} r_{t} \tag{1.4}
\end{equation*}
$$

with $r_{t}$ fulfilling the following degenerate convergence criterion $\mathrm{DCC}_{b}$ :

$$
\begin{gather*}
P\left\{\left|r_{t}\right|>\varepsilon t^{-1}\right\}=o\left(t^{2+b}\right) \quad \text { for every } \varepsilon>0,  \tag{i}\\
P\left(r_{t}\left\{\left|r_{t}\right| \leqslant t^{-1}\right\}\right)=o(t),  \tag{ii}\\
P\left(r_{t}^{2}\left\{\left|r_{t}\right| \leqslant t^{-1}\right\}\right)=o\left(t^{0}\right)
\end{gather*}
$$

(For notational convenience, we have identified a set $A$ with its indicator function.)

For $a=b=0$, differentiability of $f_{t}$ in this sense is equivalent to local asymptotic normality (1.1), (1.2) and, therefore, to differentiability of $f_{t}^{1 / 2}$ in quadratic mean. The question poses itself whether in general $\mathrm{DCC}_{b^{-}}$ differentiability of $f_{t}$ at a certain rate can be described by differentiability of an appropriate root $f_{t}^{1 / c}$ in $c$-mean at a rate $o\left(t^{a}\right)$, say. The latter is the obvious generalization of (1.3) to

$$
\begin{equation*}
f_{t}^{1 / c}=1+t \frac{1}{c} g+t^{1+a} r_{t} \quad \text { with } P\left(\left|r_{t}\right|^{c}\right)=o\left(t^{0}\right) \tag{1.5}
\end{equation*}
$$

To answer this question, we first show in Theorem 2.7 that for $0 \leqslant a$ $<1$ and $b, c>0$, differentiability of a root $f_{t}^{1 / c}$ in $c$-mean at a rate $o\left(t^{a}\right)$ can be described by differentiability of another root $f_{t}^{1 / b}$ in $(b, c)$-mean at a rate $o\left(t^{a}\right)$. This means that

$$
\begin{equation*}
f_{\mathrm{t}}^{1 / b}=1+t \frac{1}{b} g+t^{1+a} r_{t} \tag{1.6}
\end{equation*}
$$

with $r_{t}$ fulfilling the following condition $R_{1+a, b, c}$ :

$$
\begin{gather*}
P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>t^{-1-a}\right\}\right)=o\left(t^{(c-b)(1+a)}\right),  \tag{i}\\
P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant t^{-1-a}\right\}\right)=o\left(t^{0}\right) . \tag{ii}
\end{gather*}
$$

The case $b=1, \quad c=2$ compares best with condition DCC. Differentiability of $f_{t}$ in $(1,2)$-mean at a rate $o\left(t^{0}\right)$ was introduced in [10] under the name weak differentiability. Theorem 2.7 shows that weak differentiability of $f_{t}$ is equivalent to differentiability of $f_{t}^{1 / 2}$ in quadratic mean. A proof via equivalence with (1.1) is given by LeCam [7]. The equivalence remains true with rates $o\left(t^{a}\right)$, where $0 \leqslant a<1$.

For the question of comparing $\mathrm{DCC}_{b}$-differentiability with differentiability of roots in some mean with $o\left(t^{a}\right)$, however, the answer is less satisfactory. For $a>0$ we have only obtained the result that differentiability of $f_{t}^{1 / 2}$ in quadratic mean (or differentiability of $f_{t}$ in (1,2)-mean) at a rate $o\left(t^{a}\right)$, together with condition $\mathrm{DCC}_{2 a}(i)$ on the remainder, implies $\mathrm{DCC}_{2 a}{ }^{-}$ differentiability of $f_{t}$ at a rate $o\left(t^{a}\right)$. This follows from Theorems 2.7 and 2.12. Obviously, a condition $\mathrm{DCC}_{b}(i)$ with $b>0$ is not entailed by (1, 2)differentiability, whatever the rate imposed there. (The case $b=0$ is distinguished by the feature that (1, 2)-differentiability of $f_{t}$ automatically implies $\mathrm{DCC}_{0}(i)$ for the remainder.) As noted above, however, condition $\mathrm{DCC}_{b}(i)$ is necessary for rates of the form (1.2). Hence for higher order considerations $\mathrm{DCC}_{b}$-differentiability of $f_{t}$ seems to be better suited than differentiability of roots in some mean.

## 2. RESULTS

Let $P$ be a fixed probability measure on a measurable space ( $X, \mathscr{A}$ ), and $V \subset(0, \infty)$ arbitrary. For $t \in V$ let $P_{t}$ be a probability measure with $P$-density $f_{t}$. We think of $P_{t}, t \in V$, as a path converging to $P$ as $t \rightarrow 0$. Such a concept is, of course, void unless 0 is an accumulation point of $V$.

A definition of differentiability will be based on the following convergence concept.
2.1. Definition. Let $a \geqslant 0$ and $b, c>0$. For $t \in V$ let $r_{t}: X \rightarrow \boldsymbol{R}$ be measurable functions. We say that $r_{t}, t \in V$, fulfills $R_{a, b, c}$ if

$$
\begin{gather*}
P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>t^{-a}\right\}\right)=o\left(t^{(c-b) a}\right),  \tag{i}\\
P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant t^{-a}\right\}\right)=o\left(t^{0}\right) . \tag{ii}
\end{gather*}
$$

Note that $r_{t}$ fulfills $R_{a, b, b}$ if and only if $P\left(\left|r_{t}\right|^{b}\right)=o\left(t^{0}\right)$.
2.2. Remark. Let $a \geqslant 0$ and $b, c>0$.
(i) If $b \leqslant c$, then $R_{a, b, c}$ implies $P\left(\left|r_{t}\right|^{b}\right)=\dot{o}\left(t^{0}\right)$, since

$$
\begin{aligned}
P\left(\left|r_{t}\right|^{b}\right) & =P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right| \leqslant t^{-a}\right\}\right)+P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>t^{-a}\right\}\right) \\
& \leqslant P\left(\left|r_{t}\right|^{\{ }\left\{\left|r_{t}\right|^{-} \leqslant t^{-a}\right\}\right)^{b / c}+o\left(t^{(c-b) a}\right)=o\left(t^{0}\right) .
\end{aligned}
$$

(ii) If $b \geqslant c$, then $P\left(\left|r_{t}\right|^{b}\right)=o\left(t^{0}\right)$ implies $R_{a, b, c}$,
since

$$
\begin{gathered}
P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|^{\prime}>t^{-a}\right\}\right) \leqslant P\left(\left|r_{t}\right|^{b}\right)=o\left(t^{0}\right)=o\left(t^{(c-b) a}\right) \\
P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right|<t^{-a}\right\}\right) \leqslant P\left(\left|r_{t}\right|^{b}\right)^{c / b}=o\left(t^{0}\right)
\end{gathered}
$$

(iii) It is well known that $P\left(\left|r_{t}\right|^{b}\right)=o\left(t^{0}\right)$ implies $P\left(\left|r_{t}\right|^{c}\right)=o\left(t^{0}\right)$ for $b \geqslant c$; similarly, $\boldsymbol{R}_{a, b, c}$ implies $\boldsymbol{R}_{a, c, b}$.

With condition $R_{a, b, c}$ we can introduce the following differentiability concepts for functions $h_{t}$ converging to the function $h_{0} \equiv 1$ as $t \rightarrow 0$.
2.3. Definition. Let $a \geqslant 0$ and $b, c>0$. For $t \in V$ let $h_{t}: X \rightarrow[0, \infty)$ be measurable functions. We call $h_{t} ; t \in V$, differentiable in $b$-mean (resp., in ( $b, c$ )mean) at a rate $o\left(t^{a}\right)$ with derivative $g$ if

$$
h_{t}=1+t g+t^{1+a} r_{t}
$$

with $r_{t}$ fulfilling $P\left(\left|r_{t}\right|^{b}\right)=o\left(t^{0}\right)$ (resp., condition $\left.R_{1+a, b, c}\right)$.
We have found it convenient to describe differentiability by an appropriate Taylor expansion. Of course, $h_{t}$ is differentiable in $b$-mean at a rate $o\left(t^{a}\right)$ with derivative $g$ if and only if

$$
\begin{equation*}
P\left(\left|t^{-1}\left(h_{t}-1\right)-g\right|^{b}\right)^{1 / b}=o\left(t^{a}\right) \tag{2.4}
\end{equation*}
$$

2.5. Remark. For $h_{t}=f_{t}^{1 / b}$, relation (2.4) writes

$$
\begin{equation*}
P\left(\left|t^{-1}\left(f_{t}^{1 / b}-1\right)-g\right|^{b}\right)^{1 / b}=o\left(t^{a}\right) \tag{2.6}
\end{equation*}
$$

For $a=0$ and $b=2$ this reduces to differentiability of $f_{t}^{1 / 2}$ in quadratic mean, introduced by LeCam [5]. (This concept was already used by Hájek [4] who refers to a preprint of LeCam's paper.)
2.7. Theorem. Let $0 \leqslant a<1$ and $b, c>0$, and assume

$$
\begin{gathered}
P\left(|g|^{(1+a)}\left\{|g| \leqslant t^{-1}\right\}\right)=O\left(t^{0}\right), \\
P\left(|g|^{c}\left\{|g|>t^{-1}\right\}\right)=o\left(t^{c a}\right) \quad \text { if } b<c, \\
P\left(|g|^{b}\left\{|g|>t^{-1}\right\}\right)=o\left(t^{o v(c(1+a)-b)}\right) \quad \text { if } b>c .
\end{gathered}
$$

Then $h_{t}^{1 / c}$ is differentiable in c-mean at a rate $o\left(t^{a}\right)$ with derivative $\frac{1}{c} g$ if and only if $h_{t}^{1 / b}$ is differentiable in $(b, c)$-mean at a rate $o\left(t^{a}\right)$ with derivative $\frac{1}{\mathrm{~b}} \mathrm{~g}$.

In other words, the representation

$$
h_{t}^{1 / c}=1+t \frac{1}{c} g+t^{1+a} r_{t}
$$

holds with $r_{t}$ fulfilling $P\left(\left|r_{t}\right|^{c}\right)=o\left(t^{0}\right)$ if and only if the representation

$$
h_{t}^{1 / b}=1+t \frac{1}{b} g+t^{1+a} s_{t}
$$

holds with $s_{t}$ fulfilling $R_{1+a . b . c}$.
The conditions on $g$ hold if $P\left(|g|^{b v c(1+a)}\right)$ is finite. For $b<c$ the third condition follows from the second, for $b>c$ the converse holds. For $a=0$ the three conditions reduce to $P\left(|g|^{b \vee c}\right)<\infty$.
2.8. Remark. Let $c \geqslant b$. If $h_{t}^{1 / b}$ is differentiable in $(b, c)$-mean (at a rate $o\left(t^{a}\right)$ ), then, by Remark 2.2 (i), $h_{t}^{1 / b}$ is differentiable in $b$-mean (at a rate $o\left(t^{a}\right)$ ). Hence by Theorem 2.7, differentiability of $h_{t}^{1 / c}$ in $c$-mean implies differentiability of $h_{t}^{1 / b}$ in $b$-mean (at the same rate). A direct proof of this consequence for $h_{t}=f_{t}$ and $a=0$ is given by Pukelsheim ([12], Theorem 2).
2.9. Remark. We are mainly interested in expressing differentiability of the $c$-root $f_{t}^{1 / c}$ in $c$-mean in terms of differentiability of $f_{t}$ itself. The reader may wonder why we have formulated Definition 2.3 (ii) and Theorem 2.7 for arbitrary $h_{t}$ instead of $f_{t}$. One reason is that some authors consider differentiability of $f_{t}$ instead of $f_{t}^{1 / c}$ in $c$-mean ${ }^{1}$.

By Remark 2.2 (ii), differentiability of $f_{t}$ in $c$-mean is stronger than differentiability of $f_{t}$ in $(1, c)$-mean and hence, by Theorem 2.7, stronger than differentiability of $f_{t}^{1 / c}$ in $c$-mean. Applying Theorem 2.7 for $a=0, b=c^{2}$, and $h_{t}=f_{t}^{c}$, we obtain that $f_{t}$ is differentiable in $c$-mean with derivative $g$ if and only if $f_{t}^{1 / c}$ is differentiable in $\left(c^{2}, c\right)$-mean with derivative $\frac{1}{c} g$. In particular, $f_{t}$ is differentiable in quadratic mean with derivative $g$ if and only if $f_{t}^{1 / 2}$ is differentiable in $(4,2)$-mean with derivative $\frac{1}{2} g$.

To compare differentiability in $(1,2)$-mean with $\mathrm{DCC}_{b}$-differentiability, we derive below a relation between the conditions $R_{1+a, 1,2}$ and $\mathrm{DCC}_{2 a}$ defined in the Introduction.

We note first that under $\mathrm{DCC}_{2 a}(i)$, the following two conditions are equivalent:

$$
\begin{gather*}
P\left(r_{t}\left\{\left|r_{t}\right| \leqslant d t^{-1-a}\right\}\right)=o\left(t^{1+a}\right),  \tag{2.10}\\
P\left(r_{t}\left\{\left|r_{t}\right| \leqslant t^{-1}\right\}\right)=o\left(t^{1+a}\right) . \tag{2.11}
\end{gather*}
$$

This follows from

$$
P\left(\left|r_{t}\right|\left\{t^{-1}<\left|r_{t}\right| \leqslant d t^{-1-a}\right\}\right)<d t^{-1-a} P\left\{\left|r_{t}\right|>t^{-1}\right\}=o\left(t^{1+a}\right) .
$$

Observe that (2.11) is stronger than DCC (ii).
This remark, together with the following theorem, implies that $\mathrm{DCC}_{2 a^{-}}$

[^0]differentiability of $f_{t}$ at a rate $o\left(t^{a}\right)$ follows from (1,2)-differentiability of $f_{t}$ at a rate $o\left(t^{a}\right)$, augmented by condition $\mathrm{DCC}_{2 a}(i)$ on the remainder.
2.12. Theorem. Let $f_{t}=1+t g+t^{1+a} r_{t}$ with $P(g)=0$ and
$$
P\left(g\left\{g>t^{-1}\right\}\right)=o\left(t^{1+2 a}\right)
$$
and $r_{t}$ fulfilling $\mathrm{DCC}_{2 a}(i)$. Then $r_{t}$ fulfills $R_{1+a, 1,2}$ if and only if $r_{t}$ fulfills $\mathrm{DCC}(\mathrm{iii})$ and (2.11).

The proof is based on the following lemma.
2.13. Lemma. Let $f_{t}=1+t g+t r_{t}$ with $P(g)=0$ and

$$
\begin{gathered}
P\left(g\left\{g>t^{-1}\right\}\right)=o\left(t^{1+b}\right) \\
P\left(r_{t}\left\{\left|r_{t}\right| \leqslant 2 t^{-1}\right\}\right)=o\left(t^{1+b}\right)
\end{gathered}
$$

Then $P\left(\left|r_{t}\right|\left\{\left|r_{t}\right|>2 t^{-1}\right\}\right)=o\left(t^{1+b}\right)$.
2.14. Remark. Let $f_{t}^{1 / 2}$ be differentiable in quadratic mean at a rate $o\left(t^{a}\right)$ with derivative $\frac{1}{2} g$. Assume

$$
\begin{gathered}
P\left(|g|^{2(1+a)}\left\{|g| \leqslant t^{-1}\right\}\right)=o\left(t^{0}\right) \\
P\left(g^{2}\left\{|g|>t^{-1}\right\}\right)=o\left(t^{2 a}\right)
\end{gathered}
$$

Then, by Theorem 2.7, $f_{t}$ is differentiable in (1,2)-mean at a rate $o\left(t^{a}\right)$ with derivative $g$. If the remainder term fulfills, in addition, $\mathrm{DCC}_{2 a}(i)$, then, by Theorem 2.12, $f_{t}$ is also $\mathrm{DCC}_{2 a}$-differentiable at a rate $o\left(t^{a}\right)$. As indicated in the Introduction, this is sufficient for local asymptotic normality of the form

$$
\sum_{v=1}^{n} \log f_{n}-1 / 2\left(x_{v}\right)=n^{-1 / 2} \sum_{v=1}^{n} g\left(x_{v}\right)-\frac{1}{2} P\left(g^{2}\right)+R_{n}(x)
$$

with $P^{n}\left\{\left|R_{n}\right|>\varepsilon n^{-a^{\prime} / 2}\right\}=o\left(n^{-a}\right)$ for every $\varepsilon>0$ and every $a^{\prime}<a$. With $a^{\prime}$ replaced by $a$, this is the rate needed by Bickel et al. [2].

It turns out that for $a<1 / 2$ the conditions on $g$ are just sufficient for an appropriate normal convergence rate $o\left(n^{-a}\right)$ of the log-likelihood ratios. For $\varepsilon_{t} \downarrow 0$ slowly enough we still have

$$
P\left(g^{2}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right)=o\left(t^{2 a}\right)
$$

Hence by a theorem of Osipov [8] (see also [9], p. 118, Theorem 8), the distribution function of

$$
n^{-1 / 2} \sum_{v=1}^{n} g\left(x_{v}\right)
$$

under $P^{n}$ converges uniformly to the normal distribution function with variance $P\left(g^{2}\right)$ at a rate $o\left(n^{-a}\right)$ for $a<1 / 2$ and $O\left(n^{-1 / 2}\right)$ for $a=1 / 2$. No better rates are obtained if the conditions on $g$ are replaced by the sufficient condition that $P\left(|g|^{2(1+a)}\right)$ is finite.

## 3. PROOFS

We need the following properties of $R_{a, b, c}$.
3.1. Remark. (i) Let $b \leqslant c$. If $r_{t}$ fulfills $R_{a, b, c}$, then there exist $\varepsilon_{t} \downarrow 0$ and $e_{t} \uparrow \infty$ such that $\varepsilon_{t} \leqslant d_{t} \leqslant e_{t}$ implies

$$
\begin{gather*}
P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>d_{t} t^{-a}\right\}\right)=o\left(t^{(c-b) a}\right),  \tag{3.2}\\
P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant d_{t} t^{-a}\right\}\right)=o\left(t^{0}\right) . \tag{3.3}
\end{gather*}
$$

Conversely, if (3.2), (3.3) hold for arbitrary $d_{t}$, then $r_{t}$ fulfills $R_{a, b, c}$.
(ii) Let $b>c$. If $r_{t}$ fulfills $R_{a, b, c}$, then (3.2), (3.3) hold for arbitrary $d_{t}$. Conversely, if (3.2), (3.3) hold for $d_{t}$ bounded and bounded away from 0 , then $r_{t}$ fulfills $R_{a, b, c}$.

Proof. (i) Assertion (i) follows easily from the two inequalities

$$
\begin{aligned}
P\left(| r _ { t } | ^ { b } \left\{\left|r_{t}\right|\right.\right. & \left.\left.>\varepsilon t^{-a}\right\}\right)-P\left(\mid r_{t} t^{b}\left\{\left|r_{t}\right|>e t^{-a}\right\}\right) \\
& =P\left(\left|r_{t}\right|^{b}\left\{e t^{-a} \geqslant\left|r_{t}\right|>\varepsilon t^{-a}\right\}\right) \\
& \leqslant \varepsilon^{b-c} t^{(c-b) a} P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant e t^{-a}\right\}\right)
\end{aligned}
$$

and

$$
\begin{aligned}
P\left(| r _ { t } | ^ { c } \left\{\left|r_{t}\right|\right.\right. & \left.\left.\leqslant e t^{-a}\right\}\right)-P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant \varepsilon t^{-a}\right\}\right) \\
& =P\left(\left|r_{t}\right|^{c}\left\{\varepsilon t^{-a}<\left|r_{t}\right|^{-a} t^{-a}\right\}\right) \\
& \leqslant e^{c-b} t^{(b-c) a} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>\varepsilon t^{-a}\right\}\right) .
\end{aligned}
$$

(ii) The case $b>c$ is similar to the case $b \leqslant c$.
3.4. Remark. $R_{a, b, c}$ is additive.

Proof. Let $r_{t}$ and $s_{t}$ fulfill $R_{a, b, c}$.
(i) We have

$$
\begin{aligned}
P\left(| r _ { t } + s _ { t } | ^ { b } \left\{\left|r_{t}+s_{t}\right|>\right.\right. & \left.\left.2 t^{-a}\right\}\right) \leqslant 2^{b} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}+s_{t}\right|>2 t^{-a}\right\}\right)+ \\
& +2^{b} P\left(\left|s_{t}\right|^{b}\left\{\left|r_{t}+s_{t}\right|>2 t^{-a}\right\}\right)=o\left(t^{(c-b) a}\right),
\end{aligned}
$$

since

$$
\begin{aligned}
P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}+s_{t}\right|>2 t^{-a}\right\}\right) & \leqslant P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right| \leqslant t^{-a},\left|s_{t}\right|>t^{-a}\right\}\right)+P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>t^{-a}\right\}\right) \\
& \leqslant t^{-b a} P\left\{\left|s_{t}\right|>t^{-a}\right\}+o\left(t^{(c-b) a}\right) \\
& \leqslant t^{(c-b) a} P\left(\left|s_{t}\right|^{b}\left\{\left|s_{t}\right|>t^{-a}\right\}\right)+o\left(t^{(c-b) a}\right)=o\left(t^{(c-b) a}\right)
\end{aligned}
$$

(ii) We have

$$
\begin{aligned}
P\left(| r _ { t } + s _ { t } | ^ { c } \left\{\left|r_{t}+s_{t}\right| \leqslant\right.\right. & \left.\left.2 t^{-a}\right\}\right) \leqslant P\left(\left|r_{t}+s_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant t^{-a},\left|s_{t}\right| \leqslant t^{-a}\right\}\right)+ \\
& +P\left(\left|r_{t}+s_{t}\right|^{c}\left\{\left|r_{t}+s_{t}\right|^{\mid} \leqslant 2 t^{-a},\left|r_{t}\right|>t^{-a}\right\}\right)+ \\
& +P\left(\left|r_{t}+s_{t}\right|^{c}\left\{\left|r_{t}+s_{t}\right|^{-a} \leqslant 2 t^{-a},\left|s_{t}\right|>t^{-a}\right\}\right)=o\left(t^{0}\right)
\end{aligned}
$$

since

$$
\begin{aligned}
P\left(| r _ { t } + s _ { t } | ^ { c } \left\{\left|r_{t}\right| \leqslant t^{-a}\right.\right. & \left.\left.,\left|s_{t}\right| \leqslant t^{-a}\right\}\right) \\
& \leqslant 2^{c} P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant t^{-a}\right\}\right)+2^{c} P\left(\left|s_{t}\right|^{c}\left\{\left|s_{t}\right| \leqslant t^{\frac{1}{a}}\right\}\right)=o\left(t^{0}\right)
\end{aligned}
$$

and

$$
\begin{aligned}
P\left(| r _ { t } + s _ { t } | ^ { c } \left\{\left|r_{t}+s_{t}\right|\right.\right. & \left.\left.\leqslant 2 t^{-a},\left|r_{t}\right|>t^{-a}\right\}\right) \leqslant 2^{c} t^{-c a} P\left\{\left|r_{t}\right|>t^{-a}\right\} \\
& \leqslant 2^{c} t^{(b-c) a} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>t^{\dot{-a}}\right\}\right)=o\left(t^{0}\right) .
\end{aligned}
$$

(iii) Condition $R_{a, b, c}$ for $r_{t}+s_{t}$ now follows from parts (i), (ii) of the proof and Remark 3.1.
3.5. Remark. If $r_{t}$ fulfills $R_{a, b, c}$ and $\left|s_{t}\right| \leqslant\left|r_{t}\right|$, then $s_{t}$ fulfils $R_{a, b, c}$.

Proof. Condition $R_{a, b, c}(i)$ is trivially fulfilled for $s_{t}$. For $b \leqslant c$, condition $R_{a, b, c}$ for $s_{t}$ follows from

$$
\begin{aligned}
P\left(\left|s_{t}\right|^{c}\left\{\left|s_{t}\right|^{*} \leqslant t^{-a}\right\}\right) & \leqslant P\left(\left|s_{t}\right|^{c}\left\{\left|s_{t}\right|^{*} \leqslant t^{-a},\left|r_{t}\right|>t^{-a}\right\}\right)+P\left(\left|s_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant t^{-a}\right\}\right) \\
& \leqslant t^{(b-c) a} P\left(\left|s_{t}\right|^{b}\left\{\left|r_{t}\right|^{\prime}>t^{-a}\right\}\right)+P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right|^{\left.\leqslant t^{-a}\right\}}\right\}\right. \\
& \leqslant t^{(b-c) a} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>t^{-a}\right\}\right)+o\left(t^{0}\right)=o\left(t^{0}\right)
\end{aligned}
$$

The case $b>c$ is treated similarly.
Proof of Theorem 2.7. We restrict ourselves to the case $b<c$. The case $b=c$ is trivial, and the case $b>c$ is treated as the case $b<c$.
(a). The following expansion will be used to prove both implications of the assertion. Let

$$
\begin{equation*}
h_{t}^{1 / b}=1+t \frac{1}{b} g+t^{1+a} r_{t} \tag{3.6}
\end{equation*}
$$

Then

$$
h_{t}^{1 / c}=\left(1+t \frac{1}{b} g+t^{1+a} r_{t}\right)^{b / c}
$$

For $z$ in a neighborhood of 0 we have the following Taylor expansion:

$$
\left|(1+z)^{b / c}-\left(1+\frac{b}{c} z\right)\right| \leqslant d z^{2}
$$

Let

$$
A_{t}:=\left\{|g| \leqslant \varepsilon_{t} t^{-1},\left|r_{t}\right| \leqslant \varepsilon t^{-1-a}\right\}
$$

with $\varepsilon_{t} \downarrow 0$ sufficiently slowly and $\varepsilon>0$ sufficiently small. From the Taylor expansion we obtain

$$
\begin{equation*}
h_{t}^{1 / c}=1+t \frac{1}{c} g+t^{1+a} s_{t} \tag{3.7}
\end{equation*}
$$

with

$$
\begin{align*}
&\left|s_{t}\right| \leqslant t^{-1-a} A_{t}^{c}+t^{-a} \frac{1}{\mathrm{c}}|g| A_{t}^{c}+\frac{b}{c}\left|r_{t}\right| A_{t}+  \tag{3.8}\\
&+t^{1-a} d\left(\frac{1}{b} g+t^{a} r_{t}\right)^{2} A_{t}+t^{-1-a}\left|1+t \frac{1}{b} g+t^{1+a} r_{t}\right|^{b / c} A_{t}^{c}
\end{align*}
$$

(b) Assume that $h_{t}^{1 / b}$ is differentiable in $(b, c)$-mean at a rate $o\left(t^{a}\right)$ with derivative $\frac{1}{b} g$. Then (3.6) holds with $r_{t}$ fulfilling $R_{1+a, b, c}$. Hence (3.7) holds with $s_{t}$ fulfilling (3.8). We have to prove $P\left(\left|s_{t}\right|^{c}\right)=o\left(t^{0}\right)$. We may treat each right-hand term in (3.8) separately as follows:

$$
\begin{aligned}
& t^{-c(1+a)} P\left(A_{t}^{c}\right) \leqslant t^{-c(1+a)} P\left\{|g|>\varepsilon_{t} t^{-1}\right\}+t^{-c(1+a)} P\left\{\left|r_{t}\right|>\varepsilon t^{-1-a}\right\} \\
& \leqslant \varepsilon_{t}^{-c} t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right)+ \\
& +\varepsilon^{-b} t^{(b-c)(1+a)} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>\varepsilon t^{-1-a\}}\right\}\right)=o\left(t^{0}\right) ; \\
& t^{-c a} P\left(|g|^{c} A_{t}^{c}\right)=t^{-c a} P\left(|g|^{c}\left\{|g| \leqslant \varepsilon_{t} t^{-1},\left|r_{t}\right|>\varepsilon t^{-1-a}\right\}\right)+ \\
& +t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right) \\
& \leqslant \varepsilon_{t}^{c} t^{-c(1+a)} P\left\{\left|r_{t}\right|>\varepsilon t^{-1-a}\right\}+o\left(t^{0}\right) \\
& \leqslant . \varepsilon_{t}^{c} \varepsilon^{-b} t^{(b-c)(1+a)} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>\varepsilon t^{-1-a}\right\}\right)+o\left(t^{0}\right)=o\left(t^{0}\right) ; \\
& P\left(\left|r_{t}\right|^{c} A_{t}\right) \leqslant P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant \varepsilon t^{-1-a}\right\}\right)=o\left(t^{0}\right) ; \\
& t^{c(1-a)} P\left(|g|^{2 c} A_{t}\right) \leqslant \varepsilon_{t}^{c(1-a)} P\left(|g|^{c(1+a)}\left\{|g| \leqslant \varepsilon_{t} t^{-1}\right\}\right)=o\left(t^{0}\right) ; \\
& t^{c(1-a)} t^{2 c a} P\left(\left|r_{t}\right|^{2 c} A_{t}\right) \leqslant \varepsilon^{c} P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant \varepsilon t^{-1-a}\right\}\right)=o\left(t^{0}\right) ; \\
& t^{-c(1+a)} t^{b} P\left(|g|^{b} A_{t}^{c}\right)=t^{b-c(1+a)} P\left(|g|^{b}\left\{|g| \leqslant \varepsilon_{t} t^{-1},\left|r_{t}\right|>\varepsilon t^{-1-a}\right\}\right)+ \\
& +t^{b-c(1+a)} P\left(|g|^{b}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right) \\
& \leqslant \varepsilon_{t}^{b} t^{-c(1+a)} P\left\{\left|r_{t}\right|>\varepsilon t^{-1-a}\right\} \\
& +\varepsilon_{t}^{c-b} t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right) \\
& \leqslant \varepsilon_{t}^{b} \varepsilon^{-b} t^{(b-c)(1+a)} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>\varepsilon t^{-1-a}\right\}\right)+o\left(t^{0}\right)=o\left(t^{0}\right) ; \\
& t^{-c(1+a)} t^{b(1+a)} P\left(\left|r_{t}\right|^{b} A_{t}^{c}\right)=t^{(b-c)(1+a)} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right| \leqslant \varepsilon t^{-1-a},|g|>\varepsilon_{t} t^{-1}\right\}\right) \\
& +t^{(b-c)(1+a)} P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>\varepsilon t^{-1-a}\right\}\right) \\
& \leqslant \varepsilon^{b} t^{-c(1+a)} P\left\{|g|>\varepsilon_{t} t^{-1}\right\}+o\left(t^{0}\right) \\
& \leqslant \varepsilon^{b} \varepsilon_{t}^{-c} t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right)+o\left(t^{0}\right)=o\left(t^{0}\right) .
\end{aligned}
$$

(c) Assume that $h_{t}^{1 / c}$ is differentiable in $c$-mean at a rate $o\left(t^{a}\right)$ with
derivative $\frac{1}{c} g$. We apply part (a) of the proof with $b, c$ and $r_{t}, s_{t}$ interchanged. By assumption, (3.6) holds with $s_{t}$ fulfilling $P\left(\left|s_{t}\right|^{c}\right)=o\left(t^{0}\right)$. Hence (3.7) holds with $r_{t}$ fulfilling (3.8). We have to show that $r_{t}$ fulfills $R_{1+a, b, c}$. By Remarks 3.4 and 3.5 it suffices to prove that each right-hand term in (3.8) fulfills $R_{1+a, b, c}$. Consider first $R_{1+a, b, c}(i)$. Choose $d \geqslant 1$ sufficiently large. Then

$$
P\left(\left|r_{t}\right|^{b}\left\{\left|r_{t}\right|>d t^{-1-a}\right\}\right)=o\left(t^{(c-b)(1+a)}\right)
$$

is trivially fulfilled for those terms in (3.8) which are bounded by $o\left(t^{-1-a}\right)$. The remaining terms are treated as follows:

$$
\begin{aligned}
& t^{-b a} P\left(|g|^{b} A_{t}^{c}\left\{t^{-a}|g| A_{t}^{c}>d t^{-1-a}\right\}\right) \leqslant t^{-b a} P\left(|g|^{b}\left\{|g|>t^{-1}\right\}\right) \\
& \leqslant t^{c-b(1+a)} P\left(|g|^{c}\left\{|g|>t^{-1}\right\}\right)=o\left(t^{(c-b)(1+a)}\right) \\
& \begin{array}{c}
t^{-b(1+a)} t^{c} P\left(|g|^{c} A_{t}^{c}\left\{t^{-1-a} t^{c / b}|g|^{c / b} A_{t}^{c}>d t^{-1-a}\right\}\right) \\
\quad \leqslant t^{c-b(1+a)} P\left(|g|^{c}\left\{|g|>t^{-1}\right\}\right)=o\left(t^{(c-b)(1+a)}\right) \\
t^{-b(1+a)} t^{c(1+a)} P\left(\left|s_{t}\right|^{c} A_{t}^{c}\left\{t^{-1-a} t^{c(1+a) / b}\left|s_{t}\right|^{c / b} A_{t}^{c}>d t^{-1-a}\right\}\right) \\
\\
\leqslant t^{(c-b)(1+a)} P\left(\left|S_{t}\right|^{c}\right)=o\left(t^{(c-b)(1+a)}\right)
\end{array}
\end{aligned}
$$

Consider now $R_{1+a, b, c}(i i)$. We have to prove

$$
P\left(\left|r_{t}\right|^{c}\left\{\left|r_{t}\right| \leqslant d t^{-1-a}\right\}\right)=o\left(t^{0}\right)
$$

for the right-hand terms in (3.8). (Recall that $b, c$ and $r_{t}, s_{t}$ are now interchanged in (3.8).) This is done as follows:

$$
\begin{gathered}
t^{-c(1+a)} P\left(A_{t}^{c}\right) \leqslant t^{-c(1+a)} P\left\{|g|>\varepsilon_{t} t^{-1}\right\}+t^{-c(1+a)} P\left\{\left|s_{t}\right|>\varepsilon t^{-1-a}\right\} \\
\leqslant \varepsilon_{t}^{-c} t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right)+\varepsilon^{-c} P\left(\left|s_{t}\right|^{c}\right)=o\left(t^{0}\right) ; \\
t^{-c a} P\left(|g|^{c} A_{t}^{c}\left\{t^{-a}|g| A_{t}^{c} \leqslant d t^{-1-a}\right\}\right)=t^{-c a} P\left(|g|^{c} A_{t}^{c}\right) \\
= \\
=t^{-c a} P\left(|g|^{c}\left\{|g| \leqslant \varepsilon_{t} t^{-1},\left|s_{t}\right|>\varepsilon t^{-1-a}\right\}\right)+ \\
+t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right) \\
\leqslant \varepsilon_{t}^{c} t^{-c(1+a)} P\left\{\left|s_{t}\right|>\varepsilon t^{-1-a}\right\}+o\left(t^{0}\right) \\
\leqslant \varepsilon_{t}^{c} \varepsilon^{-c} P\left(\left|s_{t}\right|\right)+o\left(t^{0}\right)=o\left(t^{0}\right) ; \\
\\
\begin{aligned}
& t^{c(1-a)} P\left(|g|^{2 c} A_{t}\left\{t^{1-a} g^{c} A_{t}\left\{\left|s_{t}\right| A_{t} \leqslant d t^{-1-a}\right\}\right) \leqslant P\left(\left|s_{t}\right|^{c}\right)=o\left(t^{0}\right) ;\right. \\
&\left.\left.\leqslant \varepsilon_{t}^{-1-a}\right\}\right) \leqslant t^{c(1-a)} P\left(|g|^{c(1+a)}\left\{|g| \leqslant t^{2 c} A_{t}\right)\right. \\
& t^{c(1-a)} t^{2 c a} P\left(\left|s_{t}\right|^{2 c} A_{t}\left\{t^{1-a} t^{2 a} s_{t}^{2} A_{t} \leqslant d t^{-1-a}\right\}\right)=o\left(t^{0}\right) ; \\
& \leqslant t^{c(1+a)} P\left(\left|s_{t}\right|^{2 c}\left\{\left|s_{t}\right| \leqslant \varepsilon t^{-1-a}\right\}\right) \leqslant \varepsilon^{c} P\left(\left|s_{t}\right|^{c}\right)=o\left(t^{0}\right) ;
\end{aligned}
\end{gathered}
$$

$$
\begin{aligned}
& t^{-c(1+a)} t^{c^{2} / b} P\left(|g|^{2^{2} / b} A_{t}^{c}\left\{t^{-1-a} t^{c / b}|g|^{c / b} A_{t}^{c} \leqslant d t^{-1-a}\right\}\right) \\
& \leqslant t^{c^{2} / b-c(1+a)} P\left(|g|^{2^{2} / b}\left\{\left|s_{t}\right|>\varepsilon t^{-1-a},|g| \leqslant d^{b / c} t^{-1}\right\}\right)+ \\
& +t^{c^{2} / b-c(1+a)} P\left(|g|^{2 / b}\left\{\varepsilon_{t} t^{-1}<|g| \leqslant d^{b / c} t^{-1}\right\}\right) \\
& \leqslant d^{c} t^{-c(1+a)} P\left\{\left|S_{t}\right|>\varepsilon t^{-1-a}\right\}+d^{c-b} t^{-c a} P\left(|g|^{c}\left\{|g|>\varepsilon_{t} t^{-1}\right\}\right) \\
& \leqslant d^{c} \varepsilon^{-c} P\left(\left|s_{t}\right|^{c}\right)+o\left(t^{0}\right)=o\left(t^{0}\right) ; \\
& t^{-c(1+a)} t^{2(1+a) / b} P\left(\left|s_{t}\right|^{2 / b} \cdot A_{t}^{c}\left\{t^{-1-a} t^{c(1+a) / b}\left|s_{t}\right|^{c / b} A_{t}^{c} \leqslant d t^{-1-a}\right\}\right) \\
& \leqslant t^{c^{2}(1+a) / b-c(1+a)} P\left(\left|s_{t}\right|^{c^{2} / b}\left\{\left|s_{t}\right| \leqslant d^{b / c} t^{-1-a}\right\}\right) \leqslant d^{c-b} P\left(\left|s_{t}\right|^{c}\right)=o\left(t^{0}\right) .
\end{aligned}
$$

Proof of Theorem 2.12. (i) Assume that $r_{t}$ fulfills DCC (iii) and (2.12). Then $r_{t}$ also fulfills (2.11) with $d=2$. By Lemma 2.13, applied for $b=2 a$ and $t^{a} r_{t}$ instead of $r_{t}$,

$$
P\left(\left|r_{t}\right|\left\{\left|r_{t}\right|>2 t^{-1-a}\right\}\right)=o\left(t^{1+a}\right)
$$

From DCC(iii) we obtain

$$
\begin{aligned}
P\left(r_{t}^{2}\left\{\left|r_{t}\right| \leqslant 2 t^{-1-a}\right\}\right) & =P\left(r_{t}^{2}\left\{t^{-1}<\left|r_{t}\right| \leqslant 2 t^{-1-a}\right\}\right)+P\left(r_{t}^{2}\left\{\left|r_{t}\right| \leqslant t^{-1}\right\}\right) \\
& \leqslant 2 t^{-1-a} P\left(\left|r_{t}\right|\left\{\left|r_{t}\right|>t^{-1}\right\}\right)+o\left(t^{0}\right)=o\left(t^{0}\right)
\end{aligned}
$$

Hence $R_{1+a, 1,2}$ holds by Remark 3.1.
(ii) Assume that $r_{t}$ fulfills $R_{1+a, 1,2}$. Since $P\left(r_{t}\right)=0$, we obtain

$$
\left|P\left(r_{t}\left\{\left|r_{t}\right| \leqslant t^{-1-a}\right\}\right)\right|=\left|P\left(r_{t}\left\{\left|r_{t}\right|>t^{-1-a}\right\}\right)\right| \leqslant P\left(\left|r_{t}\right|\left\{\left|r_{t}\right|>t^{-1-a}\right\}\right)=o\left(t^{1+a}\right) .
$$

Hence (2.10) holds, which is equivalent to (2.11). Furthermore, DCC (iii) follows trivially from $R_{1+a, 1,2}(i i)$.

Proof of Lemma 2.13. Since $f_{t} \geqslant 0$, we have $g+r_{t} \geqslant-t^{-1}$. Hence $r_{t}<-2 t^{-1}$ implies

$$
g \geqslant-t^{-1}-r_{t}>t^{-1}, \quad r_{t} \geqslant-t^{-1}-g>-2 g .
$$

We obtain

$$
0 \leqslant-P\left(r_{t}\left\{r_{t}<-2 t^{-1}\right\}\right) \leqslant 2 P\left(g\left\{g>t^{-1}\right\}\right)=o\left(t^{1+b}\right)
$$

By assumption, $P\left(r_{t}\right)=0$. Hence

$$
P\left(\left|r_{t}\right|\left\{\left|r_{t}\right|>2 t^{-1}\right\}\right)=-2 P\left(r_{t}\left\{r_{t}<-2 t^{-1}\right\}\right)-P\left(r_{t}\left\{\left|r_{t}\right| \leqslant 2 t^{-1}\right\}\right)=o\left(t^{1+b}\right) .
$$
